Introduction to language theory and compiling Project – Part

2

PARDON Mathieu DIAZ Y SUAREZ Esteban

November 2021

1 Introduction

The aim of this project is to implement a parser for the language alCOl with the help of the scanner we've already implemented in another project. To do so, we had to modify the given gramar. We also had to implement the action table of the language.

2 Modified grammar

The grammar contained no unproductive variable nor unreachable symbol so no changes had to be made at this level. However, changes have been made to take into account arithmetic operators priority (the rule $< ExprArith > \rightarrow < ExprArith > < Op > < ExprArith >$ did not allow to consider a difference between priorities). Changes have also been made to remove left-recursion of the rules deriving symbol ExprArith. Finally, derivation of if derivation rule has been left factorized to avoid having two rules deriving if with same prefix on the right hand.

Resulting grammar is presented in the first listing.

```

33
                           \rightarrow >
34
                           \rightarrow <
                           \rightarrow while <Cond> do <Code> endwhile
35
    < While>

ightarrow for [VarName] from <ExprArith> by <ExprArith> to <ExprArith> d
    <For>
    < Print >
37
                           \rightarrow print([VarName])
38 < Read >
                           \rightarrow read([VarName])
```

Grammar is LL(1) because left-recursion have been removed (derivation of If rules), no rules have common prefix in right-hand side (If rules also) and there is no rule that a look-ahead of the first element on the input couldn't resolve.

Since the classes of LL(1) and strong LL(1) grammars coincide, we can prove the above grammar is LL(1) by applying the test verifying it is strong LL(1). Test available here once it will be finished.

3 Action table

The action table is a two-dimensional table. The elements indexed in the lines are the potentials tops of stacks, the elements indexed in the columns are the potential look-ahead. The cells contains the action of the grammar the parser must perform if it matchs the look-ahead and the corresponding top of stack.

Bellow the action table helps us to know if we should match or accept terminals when they occur at the top of the stack.

4 Parser implementation

We used three Hashmaps: one to convert the rule's index in the grammar to its derivations, a second one to convert the variables to their line's index in the action table and a last one to convert the terminal to the column's index in the action table.

We implemented the parser using a recursive descent function. The tokens from the scanner where stored in a list.

We used a match Table and another table that tells us if we should match or accept terminals when they occur at the top of the stack as we already said in a previous chapter. As we can see in the action table, some tokens

5 Testing set

We tested our parser on different set of codes. The results were not the ones we expected. The small sets without conditions and loop work perfectly but not the ones with those two elements.

6 Non-implemented features

Only available datatype is Integer (no float, no strings...) PODs / containers No function implementation
No exponentiation operator
We've not implemented the Parse Tree printing feature.
